U.S. HARD RED SPRING WHEAT

Minnesota • Montana • North Dakota • South Dakota

THE ARISTOCRAT OF WHEAT

HARD RED SPRING—a specialty wheat grown primarily in the Northern Plains of the United States—stands out as the aristocrat of wheat when it comes to baking bread. The high protein content and superior gluten quality of hard red spring wheat make it ideal for use in some of the world's finest baked goods. Yeast breads, hard rolls and specialty products such as hearth breads, whole grain breads, bagels and pizza crusts look and taste their best when baked with top quality spring wheat flour. Even frozen dough products are better with spring wheat because they can be stored longer than those made with lower protein wheats.

Flour mills in the United States and around the world also use hard red spring wheat extensively as a blending wheat to increase the gluten strength in a batch of flour. Adding hard red spring to lower protein wheat improves dough handling and mixing characteristics as well as water absorption. The resulting flour can be used to make an assortment of bread products, as well as Chinese-type noodles.

2008 OVERVIEW

The overall average of the 2008 U.S. hard red spring wheat crop is a No. I Northern Spring. Production is up 13 percent compared to 2007. Three-fourths of the crop is a No. I grade as the crop boasts little to no damage and a high average test weight on a region wide basis. However, there is a wider distribution of some quality parameters in the crop this year and a lower vitreous kernel level, due to extremes in growing conditions and yields across the region.

Disease pressures were nearly non-existent as reflected in the mere 0.1 percent average damage level. The average test weight is 61 lb/bu (80.2 kg/hl) equal to last year and the five-year average, but about 10 percent of the crop falls below 57 lb/bu (75.1 kg/hl) due to severe drought conditions in some western areas. Across all production districts, the crop displays heavier 1000 KWT's and lower kernel ash levels, most notably in western areas.

Average protein is equal to last year and the five-year average at 14.3 percent despite a wider than normal spread in protein levels across the region. The distribution of protein in eastern areas shows a higher percentage of the crop below 13.5 percent protein compared to last year, while western areas show less of a comparative shift. Although protein spreads are wider in 2008, more than half of the crop is still between 13 and 15

protein, higher than last year.

Milling performance indicates an increase in extraction levels, but also a corresponding increase in flour ash and starch damage. Some of the increase in extraction levels may be due to the use of a new Buhler laboratory mill used in analyzing this year's crop, but the increased 1000 KWT in western areas and an increase in average kernel size are also likely contributing factors.

Dough performance reveals higher absorption levels that are a full percentage point higher than both last year and the five-year average. Farinograph stability indicates a much weaker mixing crop

compared to last year and the traditional levels expected from U.S. hard red spring wheat. Stability times as a whole average II minutes.

down from 22 last year and 18 for a five-year average. Region-wide dough mixing strength is weaker than average. This year's much higher yields, a cooler growing season and the absence of any notable crop stress during the growing season are all contributing factors.

Bake tests crop indicate loaf volumes that are similar to 2007, although still down from the five-year average. Bread quality factors scored very high for all factors, indicating the absence of any quality degradation due to disease pressures or harvest rains.

Buyers will find many positive attributes in the high grading 2008 hard red spring wheat crop. The wider distribution of some quality parameters needs to be considered when establishing contract specifications, and the

weaker mixing properties of the 2008 crop may require more diligent work with suppliers to guarantee buyers receive the quality that meets their needs.

SEASONAL CONDITIONS

PLANTING progress was near normal due to good weather conditions, with the exception of some delays in the eastern portion of the region. Planting was finished by the end of May, slightly ahead of average. Emergence was slower

dry conditions in the west and cool, wet conditions in the east. Extremely low subsoil and topsoil moisture supplies were an acute problem in western areas.

GROWING conditions improved in June as temperatures became warmer and adequate precipitation fell across the region. In July hot, dry conditions prevailed stressing the crop in the western areas of the region and affecting yield potential. The crop in the eastern areas of the region was not adversely affected due to adequate soil moisture levels. The one benefit of the dry conditions was lack of disease issues.

HARVEST was one to two weeks behind normal, beginning in early August. Weather conditions were nearly ideal during the majority of the harvest until rain showers disrupted a small portion of the crop near the end of harvest. The majority of the harvest was completed by mid-September.

WHEAT CHARACTERISTICS

Wheat grades, as defined by the Federal Grain Inspection Service (FGIS) of the USDA Grain Inspection, Packers and Stockyards Administration (GIPSA), reflect the general quality and condition of a representative sample. U.S. grades are based on test weight and include limits on damaged kernels, foreign material, shrunken and broken kernels, and wheat of contrasting classes. Each determination is made on the basis of the grain when free from dockage.

SUBCLASSES

Subclass is a separate marketing factor based on the number of kernels with a complete, hard and vitreous endosperm, the portion that makes flour. For hard red spring wheat the subclasses are:

- Dark Northern Spring (DNS)—at least
 75 percent or more dark, hard, vitreous kernels;
- Northern Spring (NS)—between 25 and 74 percent dark, hard, vitreous kernels;
- Red Spring (RS)—less than 25 percent dark, hard, vitreous kernels.

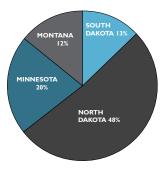

Wheat samples were obtained in Montana, North Dakota, South Dakota and Minnesota in the crop reporting areas identified in color. Samples were gathered during harvest from growers, farm bins and country elevators.

OFFICIAL U.S. GRADES AND GRADE REQUIREMENTS (Revised June 1993)

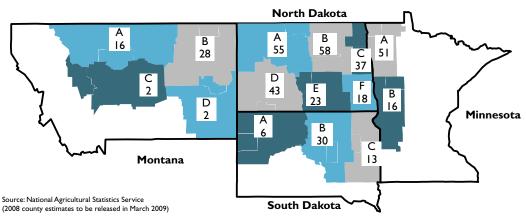

U.S. Grades **GRADING FACTORS** 2 4 5 HARD RED SPRING - MINIMUM TEST WEIGHTS 55.0 50.0 Pounds per bushel 58.0 57.0 53.0 72.5 Kilograms per hectoliter 76.4 75.1 69.9 66.0 MAXIMUM PERCENT LIMITS OF: Defects Damaged kernels 0.2 0.2 0.5 1.0 3.0 Heat (part of total) Total 2.0 4.0 7.0 10.0 15.0 0.4 0.7 1.3 3.0 5.0 Foreign material Shrunken/broken kernels 3.0 5.0 8.0 12.0 20.0 Total 1 3.0 5.0 8.0 12.0 20.0 Wheat of other classes 2 Contrasting classes 1.0 2.0 3.0 10.0 10.0 Total 3 3.0 5.0 10.0 10.0 10.0 Stones 0.1 0.1 0.1 0.1 MAXIMUM COUNT LIMITS OF: Other material Animal filth Castor beans Crotalaria seeds 2 2 2 2 Glass 0 n 0 0 3 3 3 3 3 Stones 3 Unknown foreign substances 3 3 4 Insect-damaged kernels in 100 grams 31

- U.S. Sample grade is wheat that:
- (a) Does not meet the requirements for U.S. Nos. 1, 2, 3, 4, or 5; or
- (b) Has a musty, sour, or commercially objectionable foreign odor (except smut or garlic odor); or
- (c) is heating or of distinctly low quality.
- I Includes damaged kernels (total), foreign material, and shrunken and broken kernels
- 2 Unclassed wheat of any grade may contain not more than 10.0 percent of wheat of other classes.
- 3 Includes contrasting classes.
- Includes any combination of animal filth, castor beans, crotalaria seeds, glass, stones, or unknown foreign substance.

TEST WEIGHT BY STATE 60.4 62.3 59.3

AVERAGE TOTAL DEFECTS BY STATE

AVERAGE VITREOUS KERNELS BY STATE

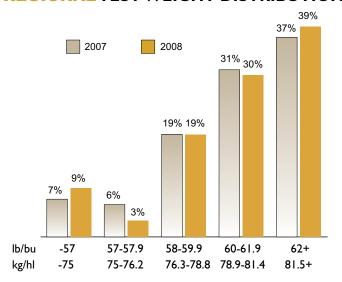

All state and regional averages have been adjusted to reflect production differences.

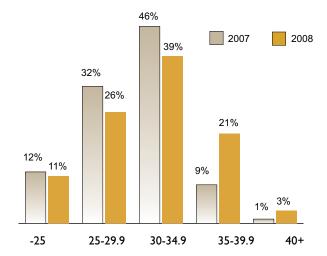

REGIONAL TEST WEIGHT DISTRIBUTION

Eighty-eight percent of 2008 samples have a test weight of 58 lb/bu (76.3 kg/hl) or greater. The regional average test weight is 61.0 lb/bu (80.2 kg/hl), similar to 2007 and the five-year average.

REGIONAL 1000 KERNEL WEIGHT DISTRIBUTION

Sixty-three percent of 2008 samples have a thousand kernel weight of 30 grams or more, higher than 2007. The regional average is 32.6 grams.

Other basic criteria beyond grading factors used to determine wheat's initial value in the marketing system include protein, moisture, dockage, falling number and ash content.

Protein is probably the most important factor in determining the value of hard red spring wheat since it relates to many processing properties. Prices for hard red spring wheat in the U.S. market are usually quoted for 14.0 percent protein (on a 12.0 percent moisture basis). Price premiums or discounts may be specified for halves, fifths and tenths of a percentage point above and below 14.0 percent, depending upon the crop's protein levels and distribution available to the market.

Moisture content is an indicator of grain storability. Wheat with low moisture content is more stable during storage. Moisture content also can be an indicator of profitability in milling.

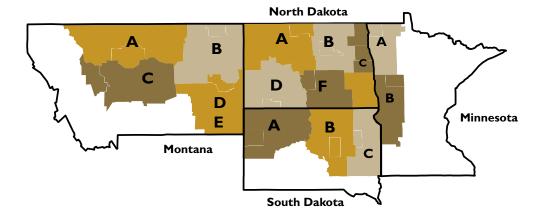

Dockage is any material easily removed from a wheat sample using standard mechanical means. Dockage removal is the first step in analyzing a sample. All other factors are determined only after dockage is removed.

Falling number indicates the soundness of wheat or its alpha-amylase activity. Low falling numbers show high activity associated with sprout damage.

Ash content primarily concentrated in the bran, is an indication of the yield that can be expected in milling white flour.

Regional vitreous kernel distribution

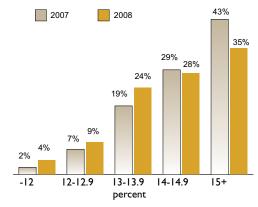

Fifty-six percent of 2008 samples have a dark, hard vitreous kernel count of 75 percent or better.

Regional falling number distribution

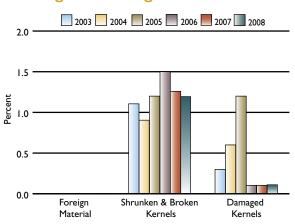

Ninety-two percent of the 2008 crop has a falling number of 350 seconds or greater.

Regional protein distribution (12% moisture basis)

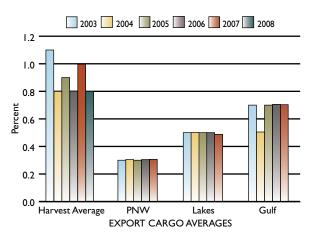

Sixty-three percent of 2008 samples have a protein content of 14.0 percent or greater, down from seventy-two last year

Regional average: total defects

Average total defects are 1.3 percent, a slight decrease from 2007.

Regional average dockage

MILLING CHARACTERISTICS

Flour is evaluated for several factors to determine overall milling efficiency, grade, soundness and functional properties.

Extraction, or the proportion of the wheat kernel that can be milled into flour, is important to mill profitability. For purposes of this survey, test milling was conducted with a Buhler laboratory mill. Results are suitable for comparison between crop years, however yields are lower than those obtained in commercial mills.

Another measure of milling efficiency and of flour grade is the ash content, or mineral residue, remaining after incineration of a sample. The lower the ash, the whiter and more refined the flour.

Starch damage measures physical damage to a proportion of the starch granules of flour. The level directly affects water absorption and dough mixing properties.

Wet gluten provides a quantitative measure of the gluten forming proteins in flour that are primarily responsible for its dough mixing and baking properties.

Falling number measures enzyme activity in flour. A fast time indicates high activity, revealing too much sugar and too little starch. Since starch provides bread's supporting structure, too much activity results in sticky dough and poor texture in finished products. Amylograph peak viscosity is another measure of enzyme activity.

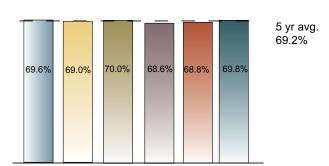

Milling: The 2008 crop samples were milled on a new **Buhler laboratory** mill, any direct comparisons of extraction, flour ash and starch damage data with the 2007 crop and the five-year average need to be kept in perspective. Internal laboratory testing of the 2008 samples when milled on the old and new Buhler laboratory mills show similar extraction and slightly higher ash with the new mill.

All state and regional averages have been adjusted to reflect production differences.

Regional average: flour extraction

The regional average extraction is 69.8 percent, higher than last year and the five-year average.

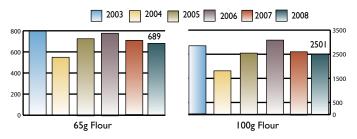

Regional average: ash content

The regional average flour ash is 0.53 percent, higher than last year and the five-year average. The use of a new Buhler lab mill for the 2008 crop accounts for some of the increase.

North Dakota В D D South Dakota

Regional average: amylograph peak viscosity

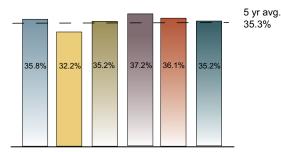

Peak viscosity averages for 2008 are slightly below last year but reflect a very sound crop.

AVERAGE WET GLUTEN BY STATE

Regional average: wet gluten

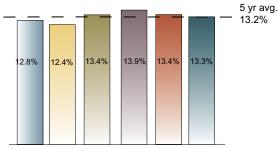

Average wet gluten content for the 2008 crop is 35.2 percent, down slightly from last year.

AVERAGE FLOUR EXTRACTION BY STATE

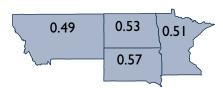

Regional average: flour protein content

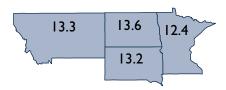

The 2008 crop produced an average flour protein content of 13.3 percent, higher than the five-year average.

AVERAGE FLOUR ASH BY STATE

AVERAGE FLOUR PROTEIN BY STATE

DOUGH CHARACTERISTICS

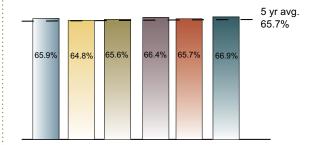

Physical characteristics of dough are evaluated to reveal useful information about variations in flour types, processing requirements and expected end-product quality.

A farinograph traces a curve during the dough mixing process to record variations in gluten development and the breakdown of gluten proteins over time. Water absorption indicates the amount of water that can be added to the flour until the dough reaches a definite consistency. Peak time indicates the number of minutes required to achieve this level of dough consistency and mixing tolerance indicates the stability of the dough. Both development time and mixing tolerance are related to dough strength. Farinograms are rated on a scale of 1 to 8, with higher values indicating strong mixing properties.

The extensigraph measures dough strength by stretching a piece of dough on a hook until it breaks. The apparatus traces a curve that measures extensibility, resistance to extension and the area beneath the curve, or energy value.

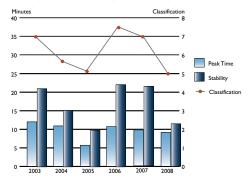

An alveograph traces a curve that measures the air pressure necessary to inflate a piece of dough to the point of rupture. The overpressure (P) value reflects the maximum pressure needed to deform the piece of dough during the inflation process and is an indication of resistance, or dough stability. The length (L) measurement reflects dough extensibility. The deformation energy (W) measurement is the amount of energy needed to inflate the dough to the point of rupture and is indicative of dough strength.

Regional average: farinogram absorption

The regional absorption is 66.9 percent, up from 2007 and the five-year averge.

Regional average: farinogram results

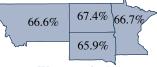

The regional average peak time is 7.1 minutes; stability, 11.0 minutes; and mixing tolerance index, 34 Brabender units; for an overall classification of 5.0 (on a 1 to 8 scale).

REGIONAL AVERGE *EXTENSIGRAM

Indicates extensibility and resistance to extension. Area beneath curve indicates the energy or work required.

REGIONAL AVERGE ALVEOGRAM

P-Curve height shows maximum pressure needed to deform dough, indicating stability. L-Length of curve reflects extensibility. W-Measurement of total energy or work needed to inflate dough.

The gluten strength in flour milled from U.S. hard red spring wheat is essential to supporting the heavy ingredients in many whole grain and artisan breads.

Although consumers make the ultimate judgement, baking tests are the final laboratory method for evaluating wheat quality. In general, a good correlation exists between loaf volume and protein quantity and quality.

Laboratory technicians also visually evaluate test loaves for crumb grain, texture and color, as well as crust color and loaf symmetry.

Above: freshly baked bread waits to cool at NDSU's Baking Laboratory.

Right Top: NDSU's Baking Laboratory

Right Bottom: Researchers at NDSU's Baking Laboratory rely on the same tools found in many bakeries such as these bread pans.

Performance characteristics often improve as buyers increase their protein specifications. To illustrate the correlation between higher protein and other quality parameters, samples of the regional crop were segregated by protein levels (all based on 12 percent moisture content):

- low (less than 13.5 percent),
- medium (13.5 percent to 14.5 percent), and
- high (more than 14.5 percent).

As protein content increased in the 2008 crop, wet gluten, absorption, mix stability and loaf volume all improved.

REGIONAL AVERAGE: PRODUCTION DISTRIBUTION BY PROTEIN RANGE

EXPORT CARGO SAMPLING

Data contained in previous sections of this report are derived from the testing of samples gathered during harvest from origination points throughout the U.S. hard red spring wheat region. The results provide an assessment of the overall quality of the crop produced in a given year.

U.S.Wheat Associates, the export market development arm for American wheat growers, furthers this information by commissioning an export cargo sampling program. The program provides an accurate representation of the supplies moving through the grain marketing and transportation system and actually reaching export points. Results show the quality levels at which U.S. wheat is realistically traded and are useful to customers in developing reasonable purchase specifications.

The Federal Grain Inspection Service oversees the program whereby all export inspection agencies at all ports collect every tenth sublot sample from every vessel of U.S. wheat shipped during three two-month time periods annually.

The hard red spring wheat samples are sent to the North Dakota State University Plant Science Department's Hard Red Spring Wheat Quality Laboratory for analysis. Average results for the past two years are at right, through the grain marketing and transportation system and actually reaching export points. Results show the quality levels at which U.S. wheat is realistically traded and are useful to customers in developing reasonable purchase specifications.

LABORATORY ANALYSIS

All quality data contained in this report are the result of testing and analysis conducted by or under the supervision of Dr. Senay Simsek, Wheat Quality Specialist, and Brent Hinsz, R. Olson, and K. McMonagle, food technologists with the Hard Red Spring Wheat Quality Laboratory in the Department of Plant Science at North Dakota State University, Fargo, USA.

COLLECTION • The North Dakota, South Dakota, Montana and Minnesota state offices of the National Agricultural Statistics Service obtained wheat samples during harvest directly from growers, farm bins and local elevators. These samples reflect the condition of the grain at the point of origin. Collection began in early August when approximately 10 to 15 percent of the hard red spring wheat had been harvested and continued until mid September when about 95 percent of the region's crop was harvested.

Sample collection was weighted by county production histories with a total of 809 samples being collected during harvest from Minnesota (102), Montana (191), North Dakota (389), and South Dakota (127).

ANALYSIS • Approximately 40 percent of the total wheat samples collected were analyzed for grade and other physical kernel characteristics. Distributions as a percentage of the harvested crop were calculated for key factors including test weight, thousand kernel weight, protein, falling number, and overall grade. Distribution results may differ from data presented in the various tables, because the latter are derived from production adjusted averages, rather than simple averages.

Quality tests, including milling, flour evaluation, physical dough and bread properties, were conducted on composite samples representing each crop reporting area. Again, all state and regional averages have been adjusted to reflect production as opposed to simple averaging.

METHODS, TERMS, SYMBOLS

WHEAT

SAMPLE COLLECTION • Each sample contained approximately 2 to 3 pounds of wheat, stored in sealed, moisture proof plastic bags.

MOISTURE • Official USDA procedure using Motomco Moisture Meter.

GRADE • Official United States Standards for Grain, as determined by a licensed grain inspector. North Dakota Grain Inspection Service, Fargo, ND, provided grades for composite wheat samples representing each crop reporting area.

VITREOUS KERNELS • Approximate percentage of kernels having vitreous endosperm.

DOCKAGE • Official USDA procedure. All matter other than wheat which can be removed readily from a test portion of the original sample by use of an approved device (Carter Dockage Tester). Dockage may also include underdeveloped, shriveled and small pieces of wheat kernels removed in properly separating the material other than wheat and which cannot be recovered by properly rescreening or recleaning.

TEST WEIGHT • American Association of Cereal Chemists Method 55-10 approved April 1961, revised October 1999. Measured as pounds per bushel (lb/bu), kilograms per hectoliter (kg/hl) = (lbs/bu X 1.292) + 1.419. *Approved Methods of the American Association of Cereal Chemists, Cereal Laboratory Methods (10th Edition), St. Paul, MN (2000).

THOUSAND KERNEL WEIGHT • Based on 10 gram sample of cleaned wheat (free of foreign material and broken kernels) counted by electronic seed counter.

KERNEL SIZE DISTRIBUTION • Percentages of the size of kernels (large, medium, small) were determined using a wheat sizer equipped with the following sieve openings:

- •top sieve—Tyler #7 with 2.92 mm opening;
- •middle sieve—Tyler #9 with 2.24 mm opening; and
- •bottom sieve—Tyler #12 with 1.65 mm opening.

PROTEIN • American Association of Cereal Chemists (AAC) Method: 46-30 (Combustion Method), expressed on dry basis and 12 percent moisture basis.

ASH • American Association of Cereal Chemists Method 08-01, approved April 1961, revised October 1999; expressed on a 14 percent moisture basis.

FALLING NUMBER • American Association of Cereal Chemists Method 56-81B, approved November 1972, revised September 1999; units of seconds (14 percent moisture basis).

SEDIMENTATION • American Association of Cereal Chemists Method 56-61A, expressed in centimeters. Approved Methods of the American Association of Cereal Chemists, (8th Edition), St. Paul, MN (1983).

FLOUR

EXTRACTION • Thoroughly cleaned wheat is tempered to 15.5 percent moisture for 16 hours and an additional 0.5 percent water is added five minutes prior to milling. The milling laboratory is controlled at 68 percent relative humidity and 72°F to 74°F. Milling is performed on a Buhler laboratory mill (Type MLU-202). Straight grade flour (of all six flour streams) is blended and reported as "flour extraction." The blended flour is rebolted through an 84 SS sieve to remove any foreign material. This product is used for the other flour quality determinations.

ASH • American Association of Cereal Chemists Method 08-01, approved April 1961, revised October 1999; expressed on a 14 percent moisture basis.

PROTEIN • American Association of Cereal Chemists (AACC) Method 46-30 (Combustion Method), expressed on a 14 percent moisture basis.

WET GLUTEN • American Association of Cereal Chemists Method 38-12, approved October 1999; expressed on a 14 percent moisture basis determined with the glutomatic instrument.

GLUTEN INDEX • American Association of Cereal Chemists Method 38-12, approved October 1999; determined with the glutomatic instrument as an indication of gluten strength.

FLOUR FALLING NUMBER • American Association of Cereal Chemists Method 56-81B, approved November 1972, revised September 1992; units of seconds. Determination is performed on 7.0 g of Buhler milled flour (14 percent moisture basis).

AMYLOGRAM • (100 g) American Association of Cereal Chemists Method 22-10. Peak viscosity reported in Brabender units (B.U.), on a 14 percent moisture basis.

(65 g) American Association of Cereal Chemists Method 22-10, modified as follows: 65 g of flour (14 percent moisture basis) are slurried in 450 ml distilled water, paddle stirrers are used with the Brabender Amylograph. Peak viscosity reported in Brabender units (B.U.), on a 14 percent moisture basis.

STARCH DAMAGE • American Association of Cereal Chemists Method 76-31. Proportion of starch granules that have incurred physical damage from milling.

PHYSICAL

DOUGH PROPERTIES

FARINOGRAM • American Association of Cereal Chemists Method 54-21; constant flour weight method, small (50 g) mixing bowl. (Flour weight 14 percent moisture basis)

ABSORPTION • Amount of water required to center curve peak on the 500 Brabender unit line, expressed on 14 percent moisture basis.

PEAK TIME • The interval, to the nearest 0.5 min, from the first addition of water to the maximum consistency immediately prior to the first indication of weakening. Also known as dough development time.

STABILITY • The time interval, to the nearest 0.5 min, between the point where the top of the curve that first intersects the 500-BU line and the point where the top of the curve departs the 500-BU line.

MIXING TOLERANCE INDEX • The difference, in Brabender units, from the top of the curve at the peak to the top of the curve measured five minutes after the peak.

VALORIMETER VALUE • An empirical, single-figure quality score based on the development time and tolerance to mixing. Derived from the farinogram by means of a special template supplied by the equipment manufacturer. Generally, stronger flours have higher valorimeter values.

CLASSIFICATION • An empirical classification incorporating peak time, stability, MTI, and general curve characteristics. A scale of I to 8 is employed with higher values indicating stronger curve types.

EXTENSIGRAM • American Association of Cereal Chemists Method 54-10, approved April 1961, revised October 1982; modified as follows: (a) 100 grams of flour (14 percent moisture basis), 2.0 percent sodium chloride (U.S.P.) and water (equal to farinograph absorption minus 2 percent) are mixed to optimum development in a National pin dough mixer; (b) doughs are scaled to 150 grams, rounded, moulded, placed in extensigram holders, and rested for 45 minutes and 135 minutes, respectively, at 30°C and 78 percent relative humidity. The dough is then stretched as described in the procedure referenced above. For conversion purposes, 500 grams equals 400 B.U.

EXTENSIBILITY • Total length of the curve at the base line in centimeters.

RESISTANCE • Maximum curve height, reported in Brabender units (B.U.).

AREA • The area under the curve is measured and reported in square centimeters.

ALVEOGRAPH • International Association of Cereal Chemists Standard No. 121. Measurement of dough extensibility and resistance to extension.

"P" • Maximal overpressure; related to dough's resistance to deformation.

"L" • Dough extensibility.

"w" • The "work" associated with dough deformation.

BAKING

PROCEDURE • American Association of Cereal Chemists Method 10-09, approved September 1985; modified as follows: (a) fungal amylase (SKB 15) replacing malt dry powder, (b) instant dry yeast (I percent) in lieu of compressed yeast, (c) 5 to 10 ppm ammonium phosphate, where added oxidants are required, (d) 2 percent shortening added. Doughs are mechanically punched using 6-inch rolls, and mechanically moulded using a National "Roll-R-Up" moulder. Baking is accomplished in "Shogren-type" pans.

BAKING ABSORPTION • Water required for optimum dough baking performance, expressed as a percent of flour weight on a 14 percent moisture basis.

DOUGH CHARACTER • Handling characteristics assessed at panning on a scale of 1 to 10 with higher scores preferred.

LOAFVOLUME • Rapeseed displacement measurement made 30 minutes after bread is removed from the oven.

CRUMB GRAIN AND TEXTURE • Visual comparison to standard using a constant illumination source. Scale of 1 to 10, the higher scores preferred.

CRUMB COLOR • Visual comparison with a standard using a constant illumination source on a scale of 1 to 10, the higher scores preferred.

CRUST COLOR • Visual comparison with a standard using a constant illumination source on a scale of 1 to 10, the higher scores preferred.

SYMMETRY • Visual comparison with a standard using a constant illumination source on a scale of 1 to 10, the higher scores preferred.

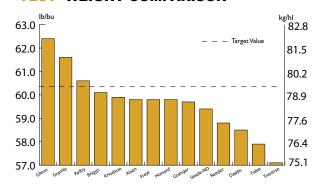

VARIETAL INFORMATION

Quality products begin with quality ingredients. In wheat, quality begins with the varieties planted. Within the hard red spring class of wheat, there are different varieties available — all with relatively uniform characteristics.

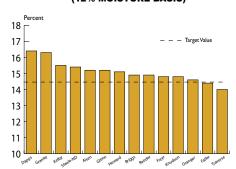

Spring wheat variety development is carried out through public breeding programs at North Dakota State University in Fargo, the University of Minnesota in St. Paul, South Dakota State University in Brookings, and Montana State University in Bozeman. Public plant breeders test varieties for performance at experiment stations across the region. Private firms also develop spring wheat varieties for the region. The two primary ones are AgriPro and Westbred.

Before any spring wheat variety is released for commercial production, it must meet or exceed current standards for the class. Prospective variety releases are evaluated for milling and baking characteristics as well as for yield, protein content, test weight, resistance to diseases and insects, and straw strength.

FARINOGRAPH STABILITY

FARINOGRAPH ABSORPTION COMPARISON (14% MOISTURE BASIS)

LOAF VOLUME COMPARISON

Target values represent regionally agreed upon goals of public and private variety development programs. Environment influences the quality of varieties across growing areas and planting years. For this reason, wheat breeders use "check" or reference varieties to evaluate quality in experimental varieties. They usually test and analyze quality data from multiple years and growing locations before a variety is released.

- 6 Willison and Dickinson, ND only.
- 7 Traditional Strong—functionality characteristic of hard red spring wheat; relatively quick mixing time, long mixing stability and tolerance to over-mixing. Extra Strong—stronger than traditional hard red spring wheat varieties; longer mixing time and very long mixing stability.
 Mellow—weaker than "traditional strong" varieties; shorter mixing time and stability.
- 8 Mill and bake quality rating based on protein content, milling performance, flour attributes, dough characteristics and baking performance.

Five stars = superior, four stars = excellent, three stars = good, two stars = average, one star = poor. Based on limited testing for end-use score.

NORTH DAKOTA

The North Dakota Agricultural Statistics Service reports leading varieties in 2008 are Glenn, Steele-ND, Freyr, Briggs and Alsen. Of the 6.8 million acres of spring wheat planted in North Dakota, the top five varieties account for 61 percent.

GLENN continues to dominate North Dakota spring wheat area with nearly 28 percent of the acres in 2008, and it is the third most popular in Minnesota. Glenn remains popular for its combination of resistance to Fusarium headblight and leaf rust, and a competitive yield. It has superior milling and baking qualities and is the industry standard for quality in public and private breeding programs.

North Dakota and third in South Dakota. It tends to be more popular in western production districts where its higher levels of resistance to leaf rust and leaf diseases, along with higher yields are finding increasing favor with producers and is replacing the variety Reeder. It is rated as having excellent milling and baking qualities.

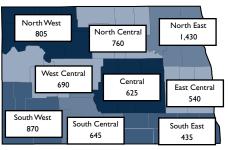

FREYR remains one of the leading production varieties in both North Dakota and Minnesota, ranking third and second, respectively. It is a variety with one of the highest levels of resistance to Fusarium headblight and consistent strong yield performance. It is rated as having very good milling and baking qualities.

MONTANA

Montana Agricultural Statistics Service reports the most popular varieties of hard red spring wheat planted in the state in 2008 are Reeder, Choteau and McNeal. Of 2.50 million acres planted, these three varieties account for 59 percent.

REEDER remains the top variety in Montana for the third straight year. It is a very high yielding variety but it is down from its peak in Montana and areas of western North Dakota due to increasing susceptibility to leaf diseases and leaf rust. It is rated as having good milling and baking quality.

CHOTEAU maintained second place in Montana and also showed strong gains in the southwest part of North Dakota. A 2003 release. it is a solid stem variety that has tolerance to the wheat stem sawfly.

MCNEAL remains in third place with 12 percent of the acres. A longtime popular variety in Montana, it has moderate resistance to the wheat streak mosaic virus and continues to show competitive yields in many areas. It's popularity is being tempered by its susceptibility to leaf rust as well as the wheat stem sawfly. McNeal has uniquely strong dough characteristics.

MINNESOTA & SOUTH DAKOTA

A Minnesota Wheat Research and Promotion Council 2008 survey indicates the most popular varieties are Knudson, Freyr, Glenn, Oklee and Briggs.

The South Dakota Agricultural Statistics Service 2008 survey shows leading varieties were Briggs, Traverse, Steele-ND, Granger and Forge.

North

Central

BRIGGS is the Minnesota counties dominant variety in responding survey South Dakota with onehalf of the acres and is the top variety in southeast North Dakota. It is a strong yielding variety that has good leaf rust resistance and is rated average for mill and bake quality. **TRAVERSE** is a 2006 release

place in South Dakota. It is noted as being one of the highest yielding varieties and is resistant to

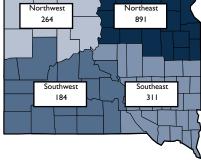

Fusarium headblight. It has low protein and is rated as poor for mill and baking quality.

KNUDSON is the leading variety in Minnesota. Its share of acres remained

stable from 2007. Its

2008* planted area (1,000 acres) 264 891

South Dakota districts

balance of resistance to Fusarium headblight, leaf rust and leaf disease and very strong yields keep it popular with producers. It is rated as having good milling and baking qualities with extra strong gluten characteristics.

OKLEE is the fourth place variety in Minnesota but is down in its share of acres from 2007 due to its moderate susceptibility to leaf rust.

HANDLING & TRANSPORTATION

The hard red spring wheat growing region in the Northern Plains has a vast network of country elevators to facilitate efficient and precise movement to domestic and export markets. On average, nearly 80 percent of the region's wheat moves to markets by rail. Duluth is the only export market serviced by a greater share of trucks. Shipments to the Pacific Northwest and Gulf export markets are almost entirely by rail, with some barge movement to the Gulf. The dominant railroad is the Burlington Northern Santa Fe, followed by the Canadian Pacific.

An increasing number of the elevators in the region are investing in facilities and rail capacity to ship 100 car units. Each rail car holds approximately 3,500 bushels (95 metric tons) of wheat. Some of the 100-car shippers have invested in "shuttle" capabilities. Shuttle-equipped facilities receive the lowest rates, sharing volume and transaction efficiencies with the railroad.

The diverse rail shipping capacities and a widespread network of elevators are strengths that buyers can capitalize on, especially as their demand heightens for more precise quality specifications and consistency between shipments. Buyers are increasingly exploring origin-specific shipments. Many international buyers now find it possible to request wheat from certain locations to optimize the quality and value of wheat they purchase.

The rail and elevator network in the U.S. hard red spring wheat region is well suited for meeting the increasing quality demands of both domestic and international customers.
